

## Java Patterns

---

Although today's discussion of expressions extends to the detail level, it is important to keep in mind that instincts for programming will be sharpened much more effectively if you pay attention to the more holistic side, concentrating on learning the idioms and patterns that implement particular problem-solving strategies. These programming patterns give you a considerable amount of power without requiring you to learn too many of their component details. This section summarizes the most important patterns, each of which is covered in more detail in Chapter 2, 3, or 4.

The first set of patterns involves getting data in and out of the computer, which provide the necessary support for the input and output phases of a typical programming task. The patterns you use depend on the type of value, as shown in the following table:

| Type           | Declaration                               | Input pattern                              |
|----------------|---|--|
| Integer        | <b>int</b> <i>var</i> = <i>value</i> ;    | <i>var</i> = <b>readInt</b> ("prompt");    |
| Floating-point | <b>double</b> <i>var</i> = <i>value</i> ; | <i>var</i> = <b>readDouble</b> ("prompt"); |
| String         | <b>String</b> <i>var</i> = <i>value</i> ; | <i>var</i> = <b>readLine</b> ("prompt");   |

The following patterns are useful in calculations:

| English   | Java (long form)                 | Java (shorthand form)  |
|---|----------------------------------|------------------------|
| Add <i>y</i> to <i>x</i> .                      | <b>x</b> = <b>x</b> + <b>y</b> ; | <b>x</b> += <b>y</b> ; |
| Subtract <i>y</i> from <i>x</i> .               | <b>x</b> = <b>x</b> - <b>y</b> ; | <b>x</b> -= <b>y</b> ; |
| Add 1 to <i>x</i> (increment <i>x</i> ).        | <b>x</b> = <b>x</b> + <b>1</b> ; | <b>x</b> ++;           |
| Subtract 1 from <i>x</i> (decrement <i>x</i> ). | <b>x</b> = <b>x</b> - <b>1</b> ; | <b>x</b> --;           |

The most helpful patterns, however, encompass programming operations on a larger scale and help you establish the overall strategy of a program. The most important ones are described in the next few sections.

### The repeat-N-times pattern: (page 101)

This pattern is the same as it was in Karel and is used for the same purpose.

```
for (int i = 0; i < N; i++) {
    statements to be repeated
}
```

In Java, however, you are allowed to use the value of the index variable **i** in the body of the loop.

### The repeat-until-sentinel pattern: (page 102)

This pattern is useful whenever you need to read in values until the user enters a particular value to signal the end of input. Such values are called **sentinels**.

```
while (true) {
    prompt user and read in a value
    if (value == sentinel) break;
    rest of body
}
```
